

Programming with Android: Calculator Example

Luca Bedogni

Marco Di Felice

Dipartimento di Informatica: Scienza e Ingegneria

Università di Bologna

Calculator: **Outline**

➤ Today:

- How to build a Calculator?
- Define the layout of the application
- Create an application that uses this layout
- Add some sort of intelligence to the application
- Test it

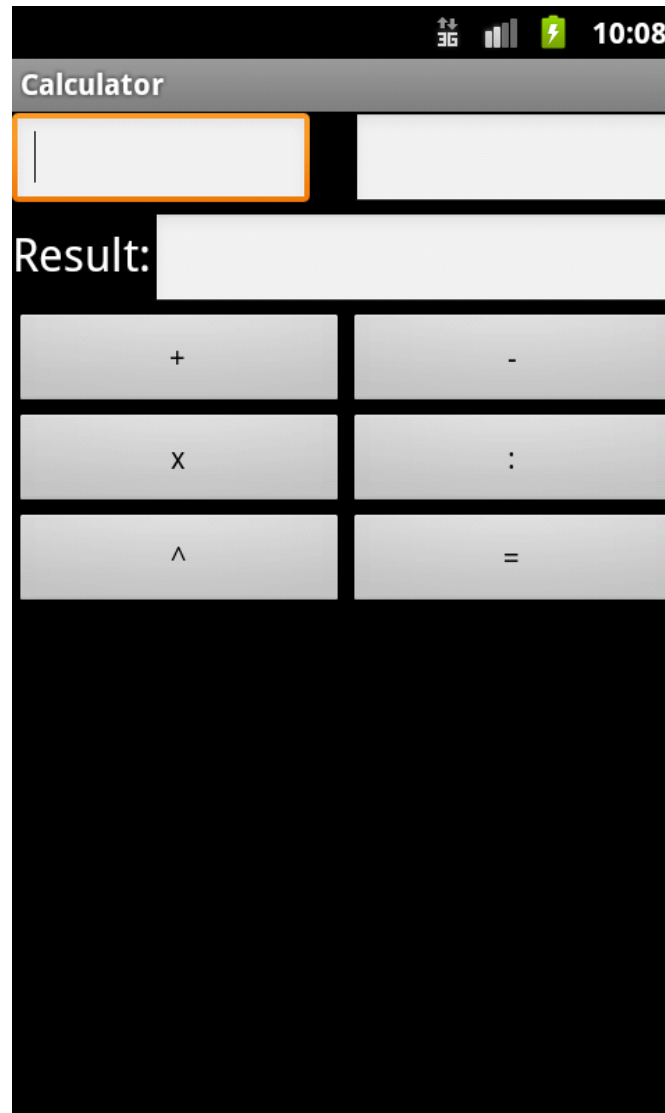

Calculator: **layout**

- ❖ Define the buttons, labels, cells and so on
- ❖ Place them on the screen
- ❖ Pay attention: Android powered phones are very different in terms of resolutions
- ❖ Try not to stick with absolute values/positioning (we will see this later)

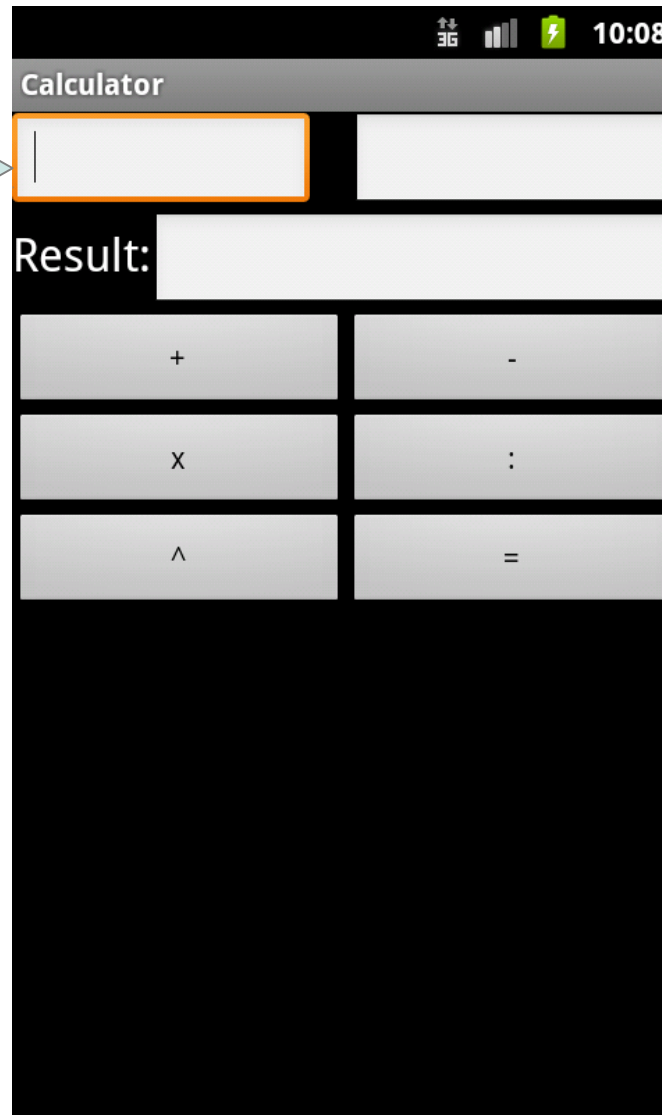

Calculator: layout definition

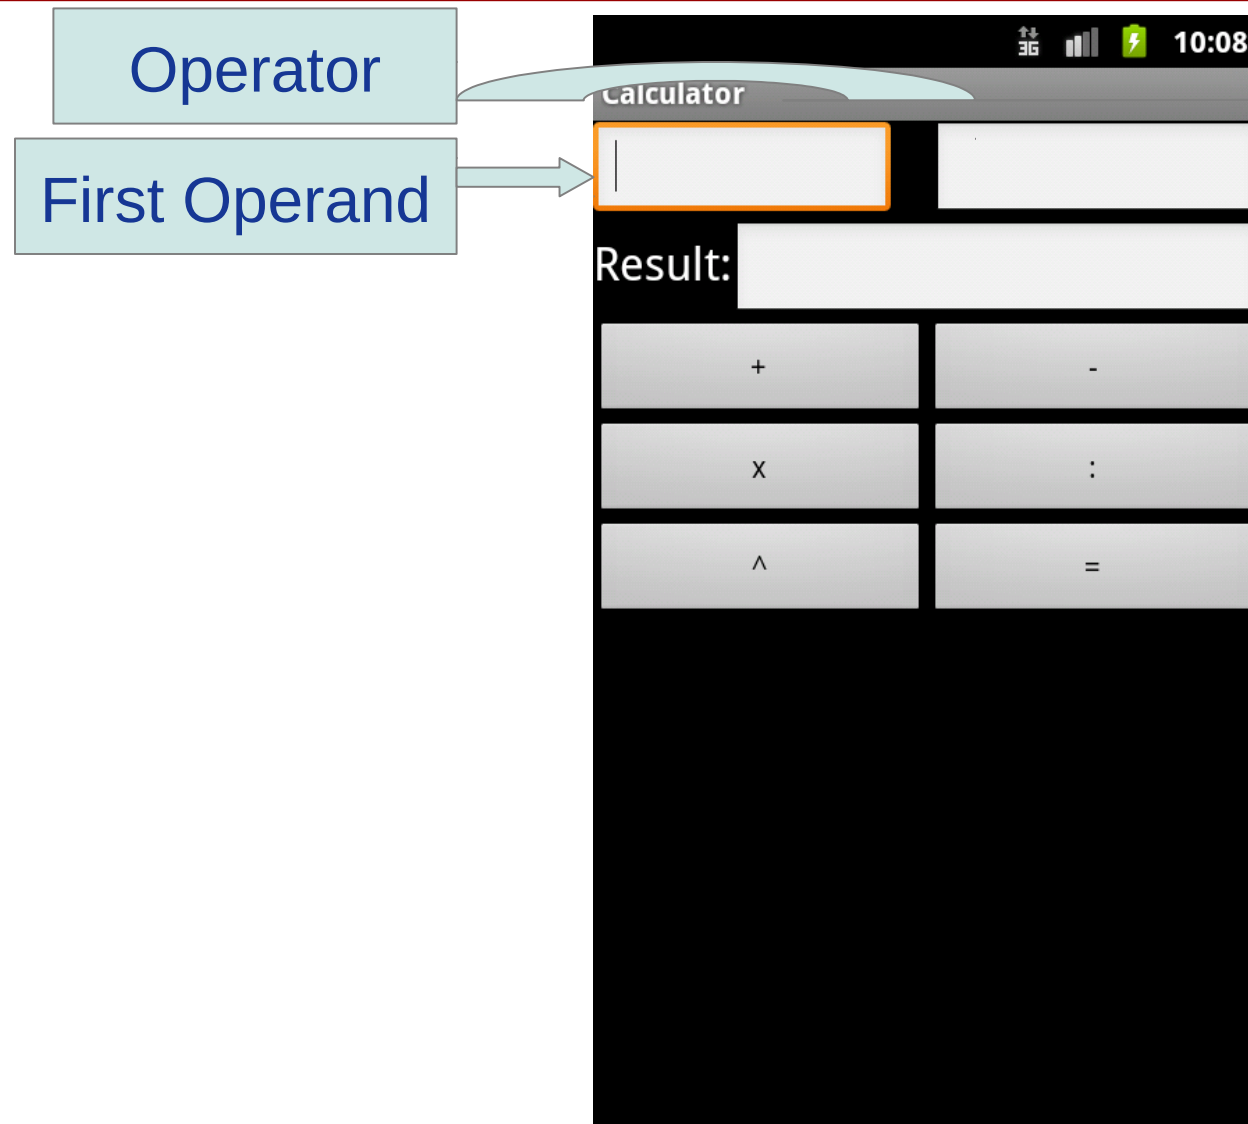

Calculator: layout definition

First Operand

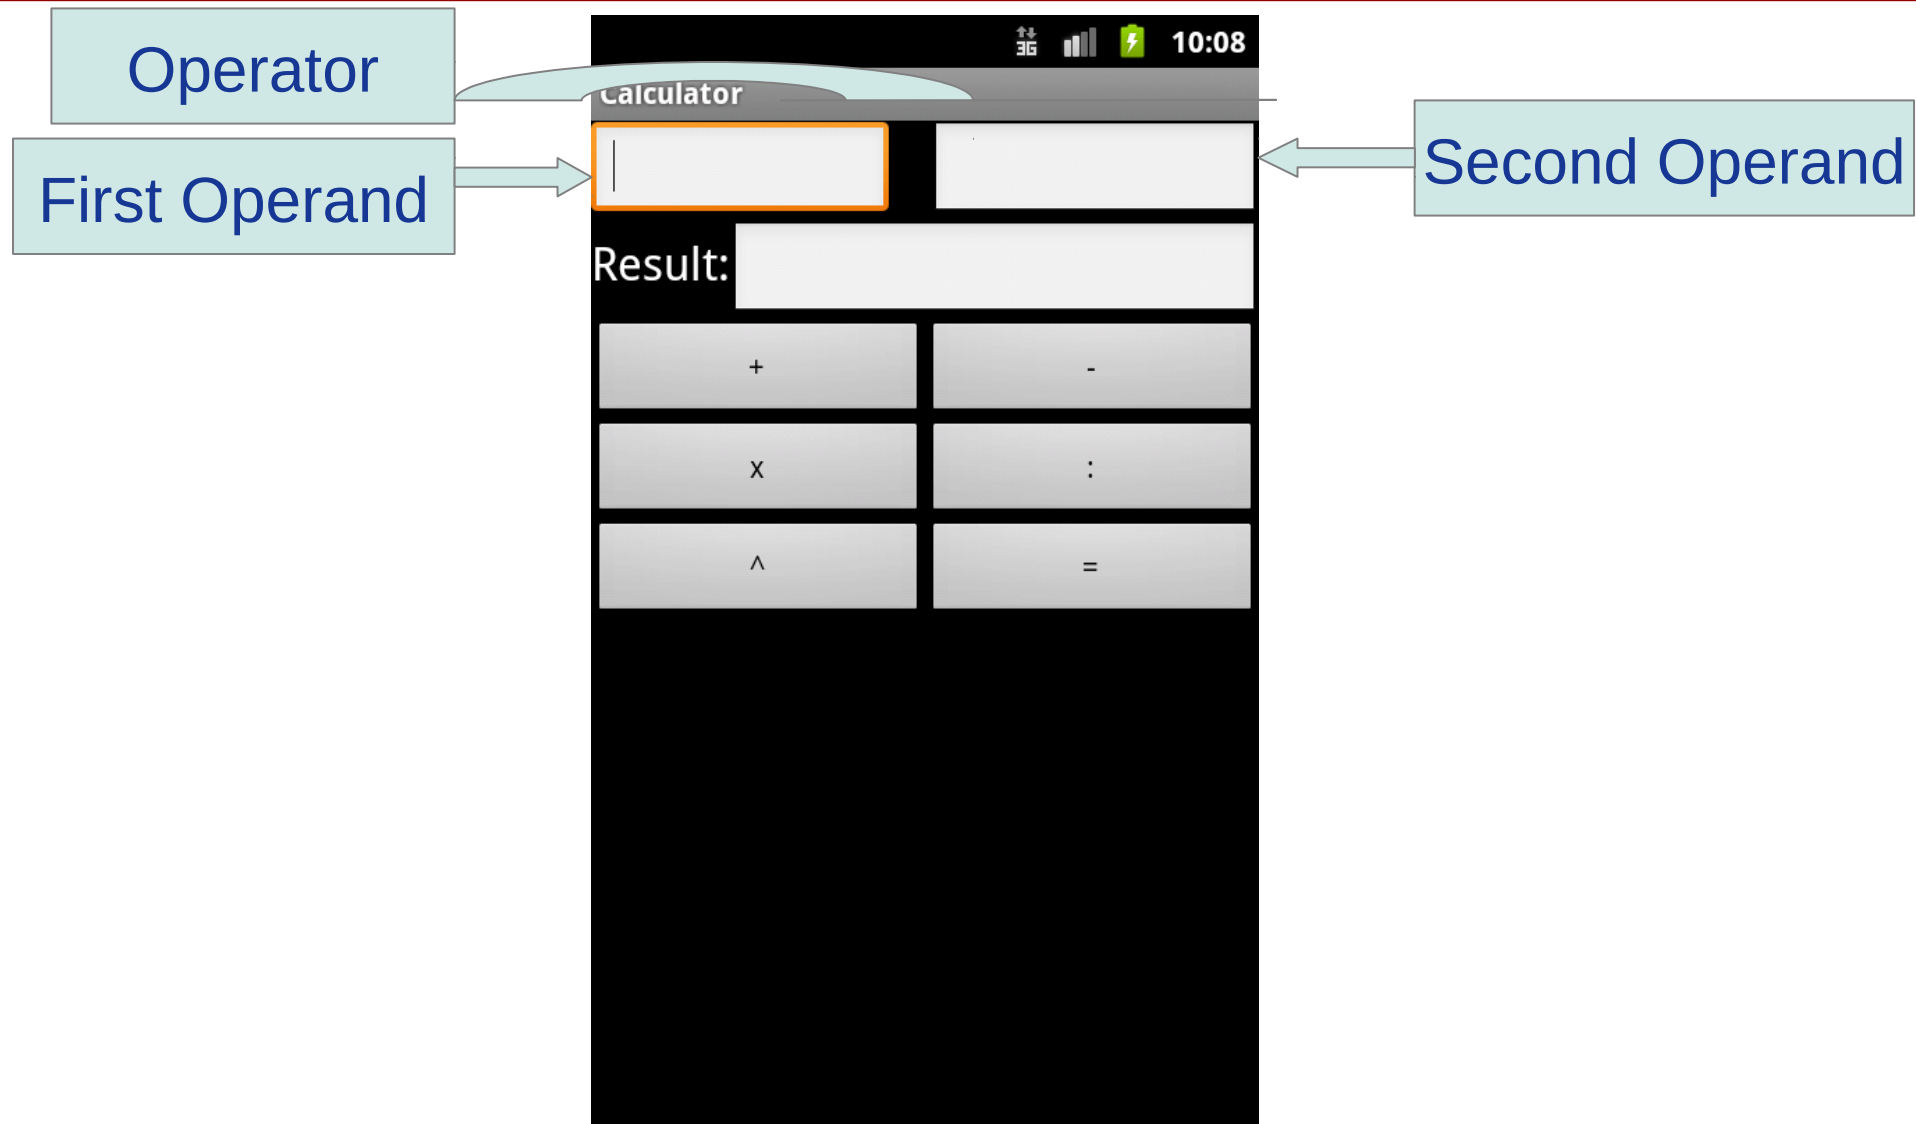

Calculator: layout definition

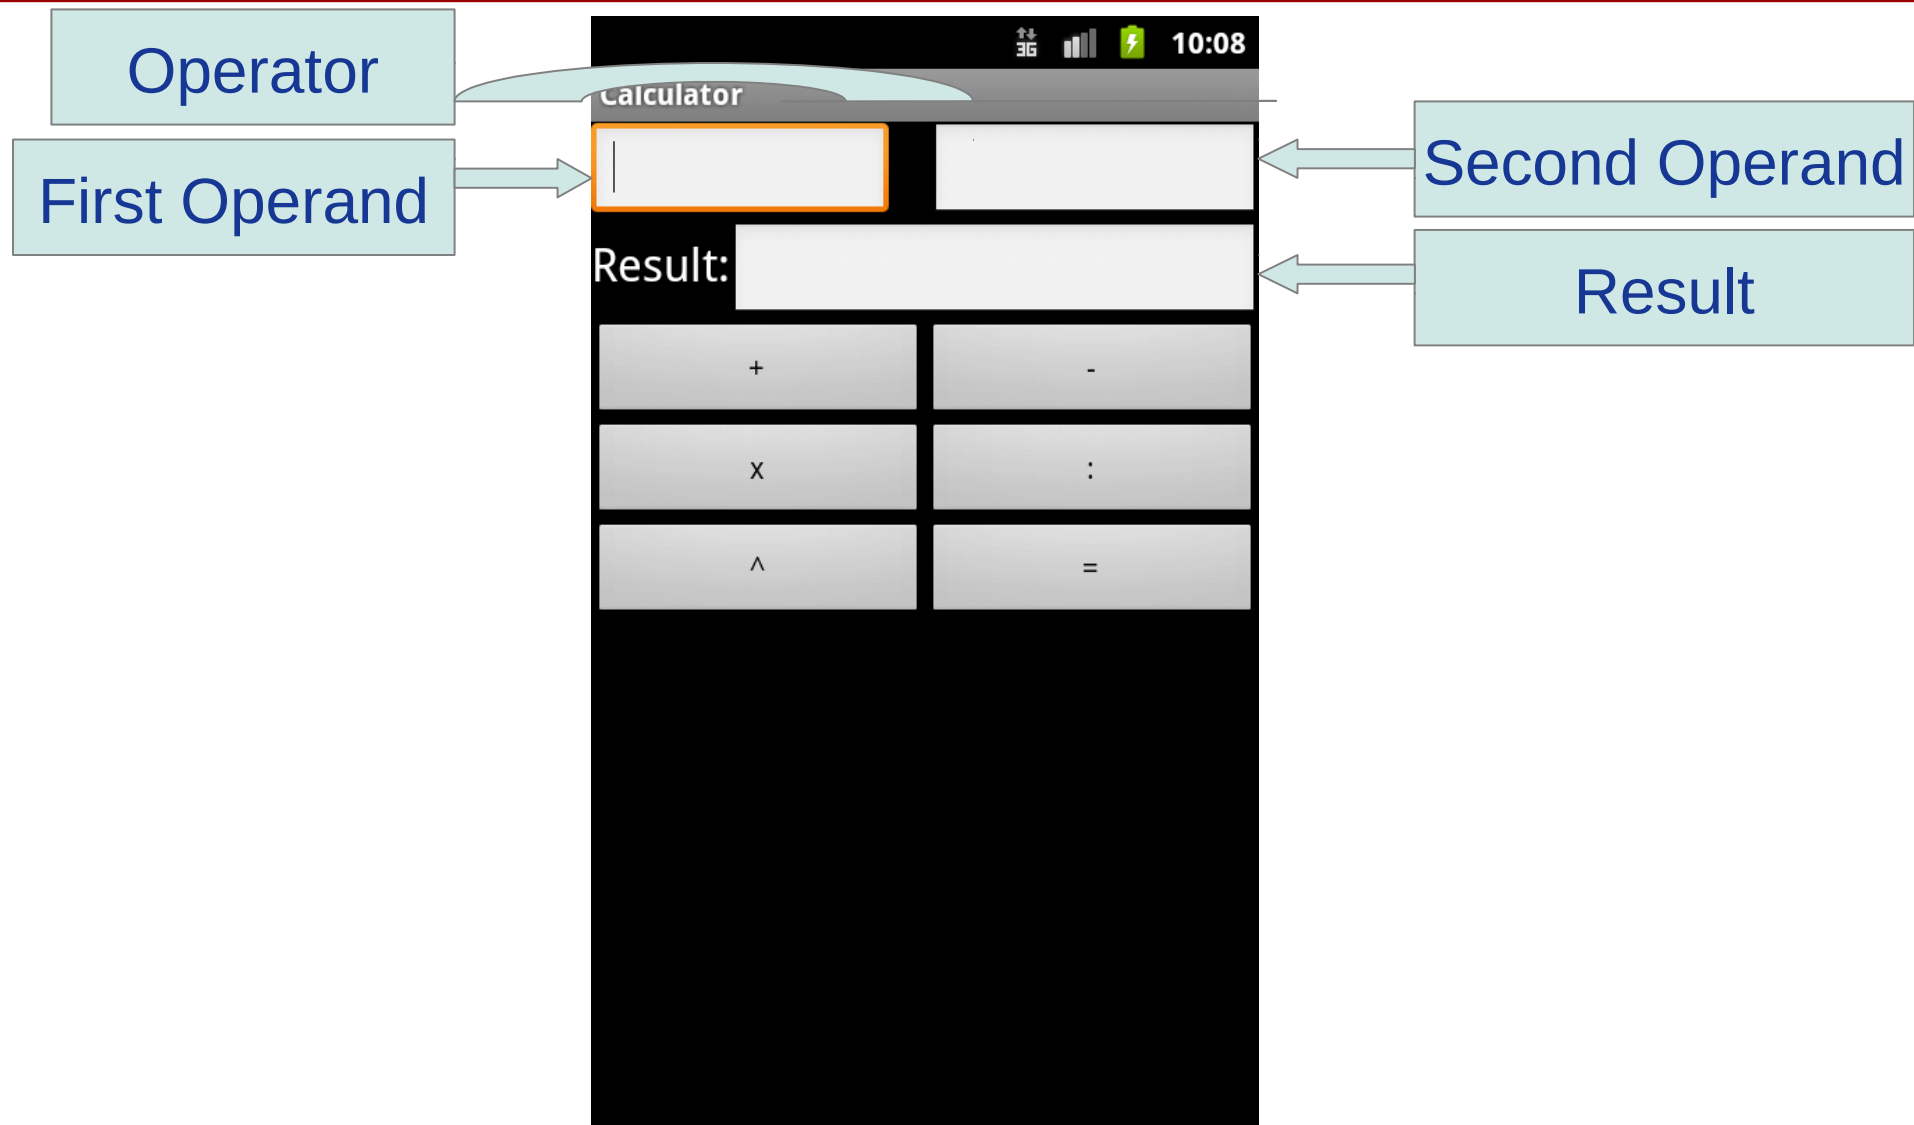

Calculator: layout definition

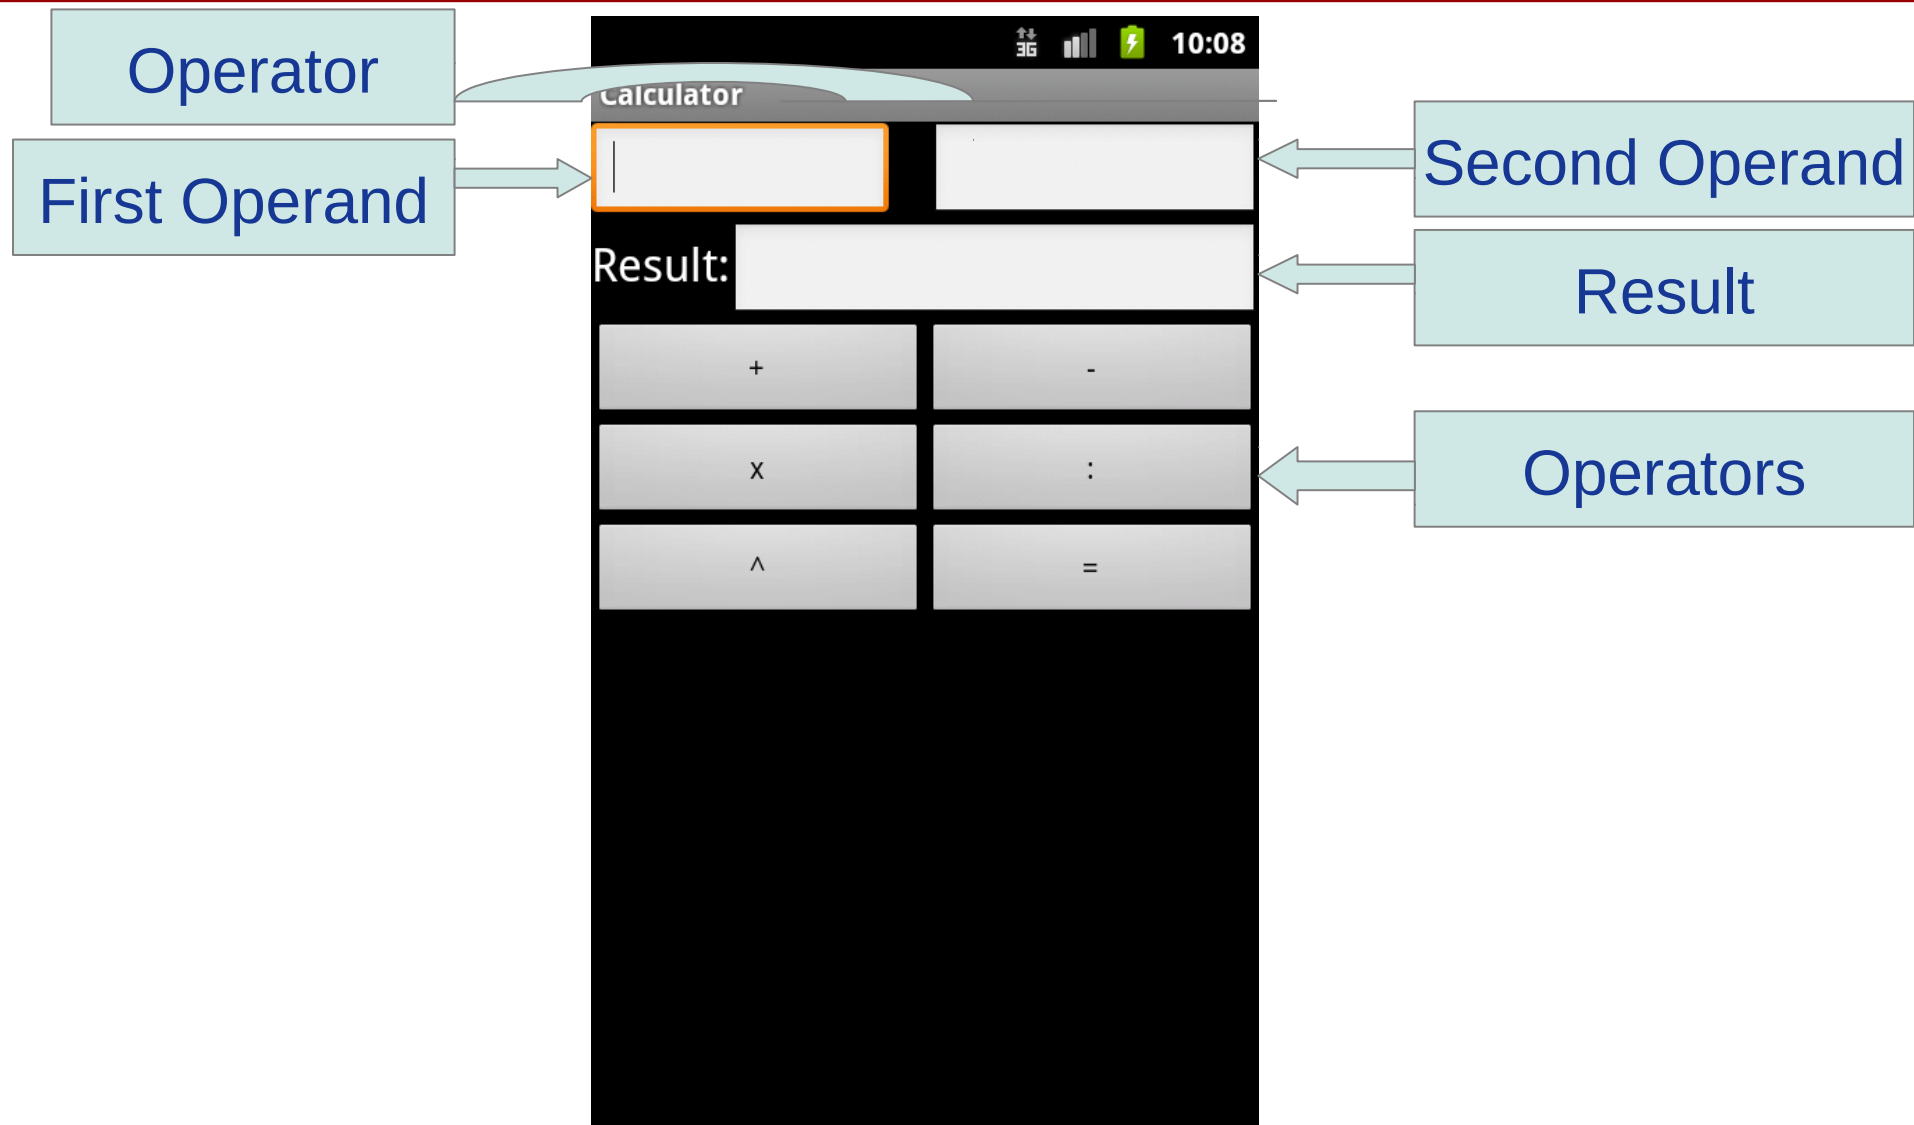

Calculator: layout definition

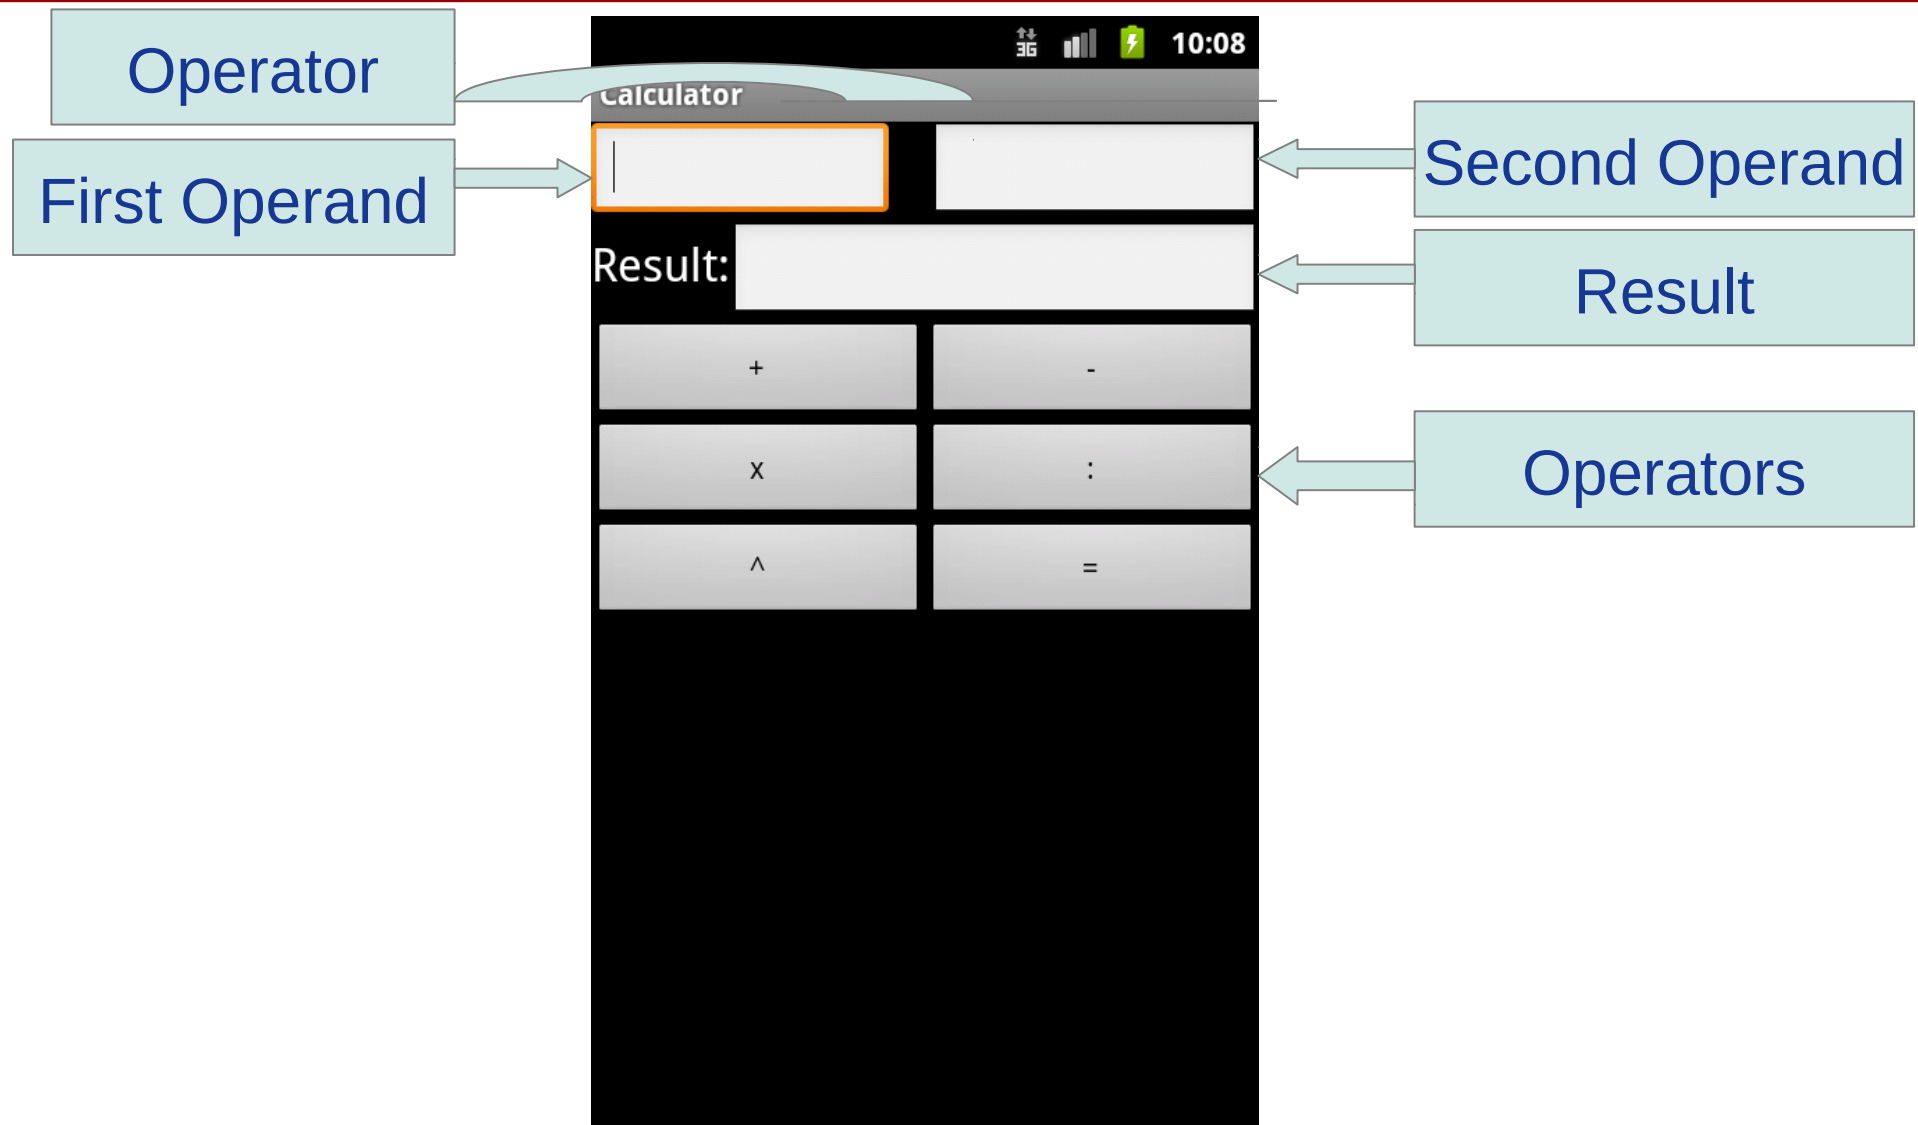

Calculator: layout definition

Calculator: layout definition

Calculator: **logic definition**

- ❖ Whenever a user selects a operand cell, a keyboard will pop up
- ❖ Pressing an operator button will switch the focus from one operand to another (except for =)
- ❖ We want to deal with float numbers

Calculator: **events**

- ❖ We want to be warned when a user touches something on the screen
 - Every time this happens, we will react with a set of actions
 - The MVC pattern is relaxed that way (pros and cons)
- ❖ We do not want the result to be focusable

Calculator: **layout building**

- ❖ We will use a set of layouts
- ❖ Layouts are grouped together following a hierarchy
- ❖ Why not absolute positioning?

Calculator: **layout building**

- ❖ We will use a set of layouts
- ❖ Layouts are grouped together following a hierarchy
- ❖ Why not absolute positioning?
 - Android has a wide range of devices
 - Wide range of resolution
 - Wide range of capabilities

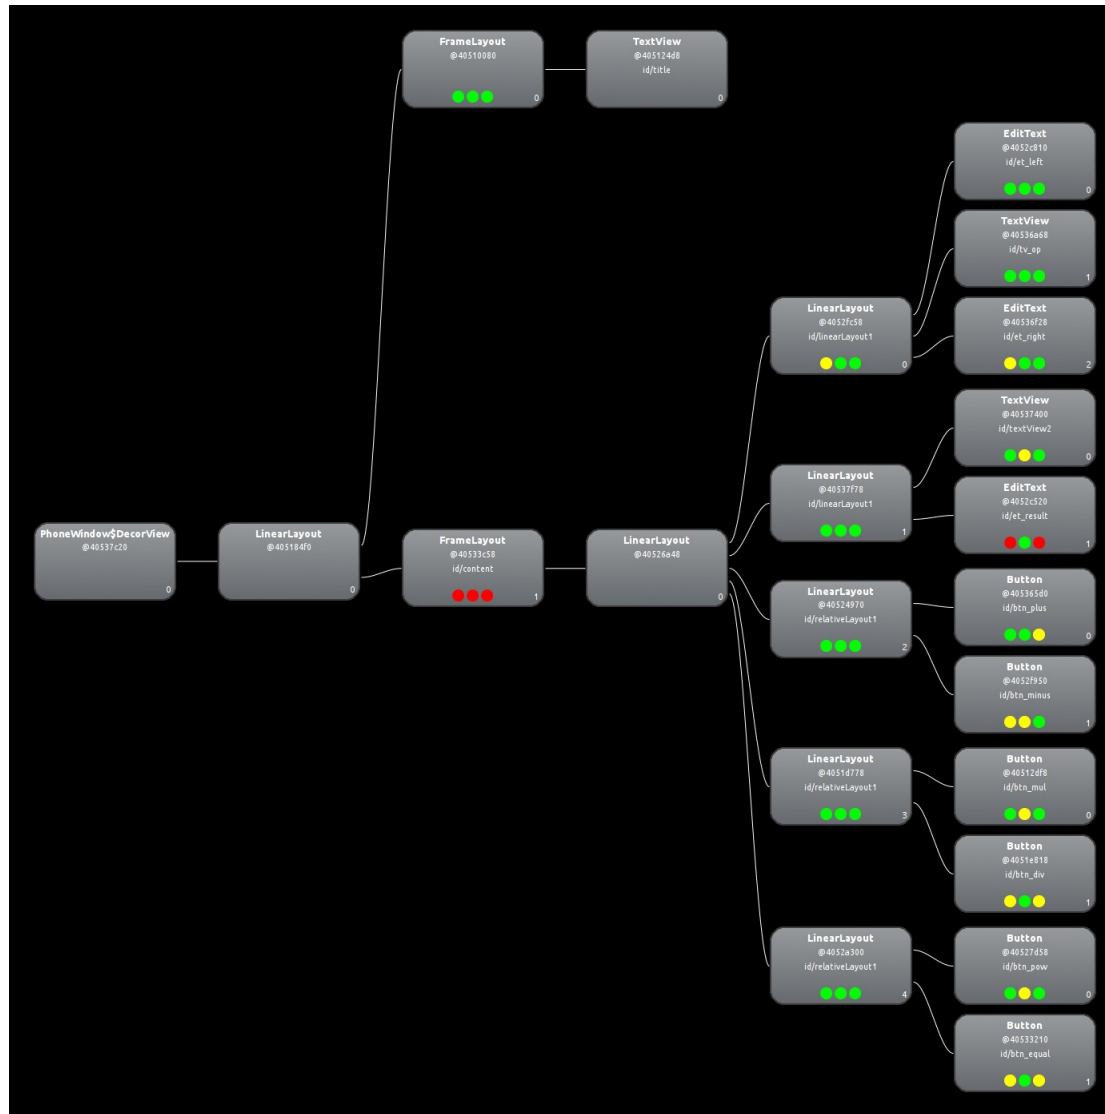

Calculator: **layout building**

- ❖ We will use a set of layouts
- ❖ Layouts are grouped together following a hierarchy
- ❖ Why not absolute positioning?
 - Android has a wide range of devices
 - Wide range of resolution
 - Wide range of capabilities

Need to build dynamic applications that performs different depending on the device they're running in.

Calculator: hierarchy viewer

Calculator: **Recap**

❖ Define a Layout

- Pay Attention to devices heterogeneity

❖ Features

- Keyboard should pop up when needed
 - Should not pop up on the result
- Switch from one cell to another when pressing operand
 - React to Events

Calculator: **start**

Let's start developing the calculator
